

Please fill in the name of the event you are preparing this manuscript for.	2022 International Petroleum Technology Conference	
Please fill in your 5-digit IPTC manuscript number.	22IPTC-22476	
Please fill in your manuscript title.	Feasibility Of CO ₂ Storage In Depleted Gas Reservoirs Exhibiting Thermal Effects During Injection	
Please fill in your author name(s) and company affiliation.		
Given Name	Surname	Company
Hussein	Hoteit	KAUST

This template is provided to give authors a basic shell for preparing your manuscript for submittal to an IPTC meeting or event. Styles have been included (Head1, Head2, Para, FigCaption, etc) to give you an idea of how your finalized paper will look before it is published by IPTC. All manuscripts submitted to IPTC will be extracted from this template and tagged into an XML format; IPTC's standardized styles and fonts will be used when laying out the final manuscript. Links will be added to your manuscript for references, tables, and equations. Figures and tables should be placed directly after the first paragraph they are mentioned in. The technical content of your paper WILL NOT be changed. Please start your manuscript below.

Abstract

Objectives/Scope: Permanent storage of carbon dioxide in deep subsurface formations is widely acknowledged as a scalable and achievable technology that can contribute significantly to the ongoing effort to limit CO₂ emissions into the atmosphere. Depleted gas reservoirs are particularly appealing for a safe and effective storage of CO₂. However, injecting CO₂ in a depleted reservoir is associated with an injectivity challenge related to CO₂ phase transition. In this work, we model the thermal and thermodynamic effects on CO₂ injectivity based on experimental data.

Methods, Procedures, Process: In this work, we analyze and model lab experiments performed to replicate the Joule-Thomson (JT) cooling for CO₂ injection in a 40ftslim-tube, reflecting the reservoir pressure and temperature conditions. We then consider a field case and evaluate the technical and economic viability of three potential solutions, including Nitrogen pre-injection to remove connate water from the wellbore vicinity, hydrate inhibitor additives, and CO₂ surface heating. We use high-resolution, full-physics simulations to capture the governing mechanisms localized near the wellbore, including the thermodynamic phase behavior from CO₂ impurity and phase transition, JT effect, brine vaporization, and corresponding salt precipitation, ice and hydrate formation, and porosity and permeability reductions.

Results, Observations, Conclusions: Geological carbon sequestration processes include entrapping CO₂ in saline aquifers and hydrocarbon reservoirs in its mobile buoyant phase and in basaltic and carbonate reservoirs in its solid phase. Each technology exhibits advantages and limitations related to the storage capacity, entrapment factors, and leakage risk. Depleted gas reservoirs offer convenient storage, where the higher density of supercritical CO₂ compared to natural gas can accommodate a mass amount of CO₂ larger than that of the initial gas in place. However, injecting CO₂ in a depleted reservoir, whose pressure is lower than the CO₂ bubble-point pressure, is associated with a major challenge related to the JT cooling effect. The JT cooling occurs when CO₂ flashes from its dense (liquid or supercritical) phase to its gas phase. This problem has been encountered in different fields in the North Sea, as reported by ConocoPhillips, BP, and Shell companies. This problem has been replicated in the lab. The provided experiments demonstrated that JT cooling could drop the temperature below the hydrate formation

temperature leading to full clogging of the porous medium and to flow interruption. This flow assurance issue may jeopardize the operational safety and the uptime of the injection process at the field conditions. Novel/Additive Information: This work provides a comprehensive study guided by a unique set of experiments and applied to a real field case to assess the feasibility and propose solutions for CO₂ storage in depleted gas reservoirs. We discuss the feasibility of various mitigation plans, including CO₂ heating, hydrate inhibitors, and reservoir pre-pressurization.
